

Private and verifiable compute continuity for agentic AI

Paving the future of artificial intelligence in the
agentic economy era.

VirtualState builds open infrastructure to turn servers into private,
persistent, licensable compute capacity backed by programmable guarantees.

VirtualState **Node** + VirtualState **Compute**

AI is no longer limited to answering. It now works for us.

The major leap is not just generating content: it is running long processes, preserving context and using tools agentially.

Reactive chatbot

- Answers a query
- Consumes resources in spikes
- Temporary or limited state
- Depends on a human session
- Conventional SLA

Persistent agent

- Maintains goals and context
- Runs long processes
- Memory, files and credentials
- Delegated budget
- Continuity, recovery and guarantees

Current infrastructure is optimized for moderate concurrency. Agents need stable and persistent environments.

A persistent agent needs a place to live.

When it keeps memory, credentials, tools and snapshots, an API or an ephemeral container is no longer enough.

Persistence

State, files, working memory, configuration and snapshots.

Privacy

Credentials, sensitive context, wallets, connectors and corporate data.

Availability

If the environment fails, the agent loses operational continuity.

Guarantees

Traditional SLAs do not automatically settle breaches.

The bottleneck is no longer just the GPU, but third-party dependencies.

VirtualState turns servers into private, persistent and licensable compute capacity.

An infrastructure layer to host the harness of persistent agents—not necessarily the LLM—with state and programmable guarantees.

VirtualState **Node**

Open-source software that turns host-machine resources into private and measurable compute environments.

VirtualState **Compute**

Commercial platform with a marketplace providing attestation, reputation, oracles, support and contractual settlement.

Privacy → Persistence → Guarantees → Marketplace → Smart contracts

An abstraction layer between heterogeneous hardware and the agentic economy.

Applications

Private AI · persistent agents · runtimes · open-source models

VirtualState Compute

Marketplace · API · reputation · billing · support · certified providers

Smart contracts + oracles

Licenses · price · downtime · collateral · buyback · heartbeat · logs

VirtualState Node

Lightweight hypervisor/runtime · sandbox manager · policy engine · metrics

Private sandbox

Isolation · state · snapshots · CPU/RAM/storage/network · encryption

Host infrastructure

Cloud · bare metal · own servers · verified third parties

VirtualState separates technical execution, availability measurement and contractual settlement.

Operational flow

1. A provider offers capacity
2. Node creates a sandbox on its machine
3. A compute license is listed
4. The client runs the agent harness
5. Our oracles measure heartbeat
6. The smart contract executes compensation if downtime exceeds the threshold

In the future, AI agents themselves may contract our services autonomously, de facto expanding our customer base exponentially.

MVP = node → sandbox → agent → privacy → oracle → contract

Open source where it creates trust. Commercial SaaS where it creates guarantees.

Separating Node and Compute maximizes adoption without giving up value capture.

VirtualState Node

- Open-source software
- Lightweight hypervisor/runtime
- Creates sandboxes
- Publishes resources
- Measures availability
- Enables auditability
- Distributable technical base

VirtualState Compute

- Commercial platform
- Capacity marketplace
- Certifies providers
- Manages reputation
- Coordinates oracles
- Settles guarantees
- Support and operational trust

Open source does not destroy the business model; it standardizes it.

Compute becomes a programmable commodity.

A compute license represents a right to use defined resources. It is not an investment or hardware ownership.

Digital Contract Card (example)

ID	VS-LIC-001
CPU	8 vCPU (2.4 GHz)
RAM	32 GB
Storage	500 GB (encrypted)
Uptime	98.5%
Downtime	Max. 2h tolerated
Privacy	Encrypted sandbox
Compensation	Deposit / auto-buyback smart contract version

What the license defines

Resources, duration, target uptime, tolerated downtime, privacy level, snapshots, collateral and compensation rules.

Design principle

Collateral does not eliminate technical risk, but it turns part of availability risk into a programmable economic obligation.

Layered privacy instead of promises.

The MVP introduces a first host-resistant layer for sensitive agent memory through obfuscation layers, without fully encrypting RAM in use, avoiding dependence on specific hardware and lowering the ecosystem entry barrier.

What it protects

- Encryption in transit
- Encryption at rest
- Encrypted snapshots
- Context separation
- In-use memory isolation

How it works

- Split trust
- Ephemeral seeds
- Epoch-based rotation
- Dynamic obfuscation
- Sensitive regions

Balancing adoption and confidentiality

Our architecture helps protect clients from malicious hosts by minimizing the attack surface without losing compatibility.

Extracting useful secrets would require an active attack during a short time window, at runtime and blind.

More decentralization requires more trust levels.

Not every node should promise the same degree of confidentiality. Privacy is an auditable mitigation model.

TPM 2.0 lets us raise trust without requiring advanced datacenter-class dedicated hardware from day one.

An MVP as a scale model of the final product.

The goal is an end-to-end vertical slice: node, sandbox, agent, practical privacy, oracle and contract.

Synthetic definition

VirtualState Node Alpha: a lightweight runtime to contain the agent's persistent harness—not the LLM—with sandbox, encryption, Memory Vault, minimal attestation, contract and oracle.

Verifiable artifacts

Recordable local demo · comparative dump · signed logs · testnet license · heartbeat · compensation for simulated downtime.

The demo that changes perception is end-to-end: node → agent → privacy → oracle → contract.

Milestone-based roadmap that creates value at every iteration.

We have just closed Phase 0. Funding can change speed and depth, but not the logical sequence of risk reduction.

Three entry points. One exit infrastructure.

Understandable initial use cases; the agentic economy as a structural category once the model gains momentum.

Private AI for companies

Open-source models and internal assistants without exposing sensitive knowledge. Data control, isolated sandbox and managed deployment.

Persistent agents

24/7 runtimes with memory, tools, snapshots, delegated budget and state recovery.

Compute capacity

Providers publish resources as usage licenses with explicit availability and programmable guarantees.

Digital continuity

Future prudential line: pausing, preserving and restoring advanced agents under rules defined by human or legal operators.

First privacy and persistence. Then guarantees. Then marketplace.

Open source for adoption. Commercial network for value capture.

VirtualState monetizes operations, support, marketplace, certification, reputation and guarantees.

Managed services

Private AI and open-source models for companies

Agent hosting

Resources, storage, snapshots and availability

Usage-based billing

CPU/RAM/storage/network/time and eventually GPU

Enterprise

Integration, compliance, dedicated deployment and support

Marketplace

Commission on licenses, rentals or settlements

Certification

Onboarding, audit, reputation and quality seals

Continuity

Standby, snapshots, recovery and state preservation

Our node lets us define and test the standard. Then the marketplace lets us monetize trust.

The ambition is high. The focus is deliberate.

The explosion of agentic AI is opening a new infrastructure category. VirtualState has already closed its thesis, architecture and roadmap. And we are ready to start building.

Agentic explosion

- More persistent agents = more demand for state, sandbox and continuity.
- Current infrastructure is still optimized for sessions, not agent populations.

Strategic window

- The category is still being defined: there is no clear standard yet for private agentic compute.
- Open-source Node + commercial Compute positions VirtualState to set that standard.

Capital = time compression

- With partial funding: 18–24 months to integrated Node Alpha.
- With sufficient funding: 12–18 months to accelerate MVP, pilots and technical validation.

Why come in now

- Coming in at pre-seed means joining before the standard, before the marketplace and before the first pilots.
- The right capital does not just accelerate the roadmap: it helps define an emerging category.

Now is the time to come in.

We are looking for allies able to accelerate the technical vertical slice and help define a new infrastructure layer for agents.

Founders

Multidisciplinary founding team: narrative, product, UX, architecture, cybersecurity and execution.
